

# JavaFX Application Structure

Tecniche di Programmazione – A.A. 2017/2018

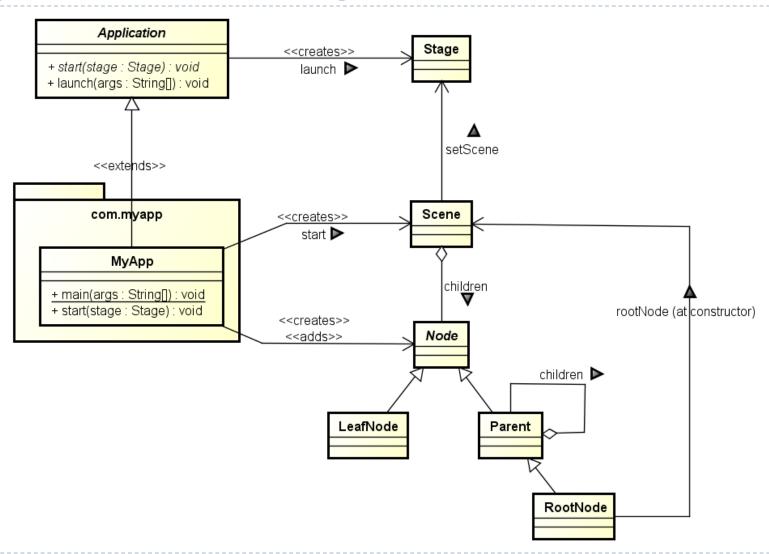

# Application structure

Introduction to JavaFX

# Empty JavaFX window

```
public class Main extends Application {
  @Override
   public void start(Stage stage) {
       Group root = new Group(); // the root is Group or Pane
       Scene scene = new Scene(root, 500, 500, Color.BLACK);
       stage.setTitle("JavaFX Demo");
       stage.setScene(scene);
       stage.show();
   public static void main(String[] args) {
       launch(args);
```

# Typical Class Diagram

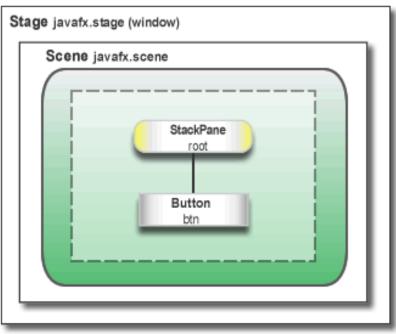

## General rules

- A JavaFX application extends javafx.application.Application
- The main() method should call Application.launch()
- The start() method is the main entry point for all JavaFX applications
  - Called with a Stage connected to the Operating System's window
- The content of the scene is represented as a hierarchical scene graph of nodes
  - Stage is the top-level JavaFX container
  - Scene is the container for all content

# Minimal example

```
public class HelloWorld extends Application {
    public static void main(String[] args) {
        launch(args);
   @Override
    public void start(Stage primaryStage) {
        primaryStage.setTitle("Hello World!");
        StackPane root = new StackPane();
        Button btn = new Button();
        btn.setText("Say 'Hello World'");
        root.getChildren().add(btn);
        primaryStage.setScene(new Scene(root, 300, 250));
        primaryStage.show();
```

# Stage vs. Scene

## javafx.stage.Stage

- The JavaFX Stage class is the top level JavaFX container.
- The primary Stage is constructed by the platform.
- Additional Stage objects may be constructed by the application.
- A stage can optionally have an owner Window.

## javafx.scene.Scene

- The container for all content in a scene graph
- The application must specify the root Node for the scene graph
- Root may be Group (clips),Region, Control (resizes)
- If no initial size is specified, it will automatically compute it

## Nodes

- The Scene is populated with a tree of Nodes
  - Layout components
  - Ul Controls
  - ▶ Charts
  - Shapes
- Nodes have Properties
  - Visual (size, position, z-order, color, ...)
  - Contents (text, value, data sets, ...)
  - Programming (event handlers, controller)
- Nodes generate Events
  - Ul events
- Nodes can be styled with CSS

## **Events**

- FX Event (javafx.event.Event):
  - Event Source => a Node
  - Event Target
  - Event Type
- Usually generated after some user action
- ActionEvent, TreeModificationEvent, InputEvent, ListView.E ditEvent, MediaErrorEvent, TableColumn.CellEditEvent, Treeltem.TreeModificationEvent, TreeView.EditEvent, WebEvent, WindowEvent, WorkerStateEvent
- You can define event handlers in your application

## **Properties**

- Extension of the Java Beans convention
  - May be used also outside JavaFX
- Encapsulate properties of an object
  - Different types (string, number, object, collection, ...)
  - Set/Get
  - Observe changes
  - Supports lazy evaluation
- Each Node has a large set of Properties

Туре	Property and Description
BooleanProperty	cancelButton
	A Cancel Button is the button that receives a keyboard VK_ESC press, if no other node in the scene of
BooleanProperty	defaultButton
	A default Button is the button that receives a keyboard VK_ENTER press, if no other node in the scene
Properties inherited	from class javafx.scene.control.ButtonBase
armed, onAction	
	Pala a sa
Properties inherited	from class javafx.scene.control.Labeled
12.0	
	ay, ellipsisString, font, graphic, graphicTextGap, labelPadding, mnemonicParsing, text, underline, wrapText
textFill, textOverrun,	
Properties inherited	text, underline, wrapText
Properties inherited	from class javafx.scene.control.Control
Properties inherited contextMenu, height, ma	from class javafx.scene.control.Control
Properties inherited contextMenu, height, ma	text, underline, wrapText  from class javafx.scene.control.Control  ixHeight, maxWidth, minHeight, minWidth, prefHeight, prefWidth, skinClassName, skin,
Properties inherited contextMenu, height, ma  Properties inherited	from class javafx.scene.control.Control  KHeight, maxWidth, minHeight, minWidth, prefHeight, prefWidth, skinClassName, skin,
Properties inherited contextMenu, height, ma	from class javafx.scene.control.Control  Ext., underline, wrapText  from class javafx.scene.control.Control  Ext., underline, wrapText

onMouseEntered, onMouseExited, onMouseMoved, onMousePressed, onMouseReleased, onRotate, onRotationFinished, onRotationStated, onSorollStated, onTouchMoved, onTouchPressed, onTouchReleased, onTouchStationary, onZoomFinished, onZoom, onZoomStated, op

# Bindings

- Automatically connect («bind») one Property to another Property
  - Whenever the source property changes, the bound one is automatically updated
  - Multiple bindings are supported
  - Lazy evaluation is supported
  - Bindings may also involve computations (arithmetic operators, if-then-else, string concatenation, ...) that are automatically evaluated
- May be used to automate UI
- May be used to connect the Model with the View

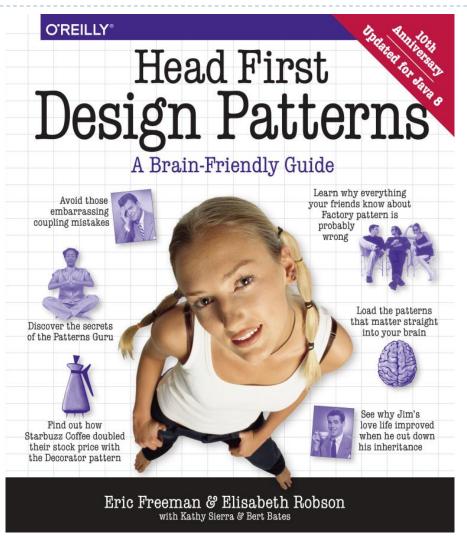

## Model-View-Controller

JavaFX programming

# Application complexity and MVC

- Interactive, graphical applications exhibit complex interaction patterns
- ▶ Flow of control is in the hand of the user
- Actions are mainly asynchronous
- How to organize the program?
- Where to store data?
- How to decouple application logic from interface details?
- How to keep in sync the inner data with the visibile interface?

# Design Patterns

# Design Patterns

- How to build systems with good OO design qualities
  - Reusable, extensible, maintainable
- Patterns: Proven solutions to recurrent problems
  - Design problems
  - Programming problems
- Adopt and combine the OO constructs
  - Interface, inheritance, abstract classes, information hiding, polymorphism, objects, statics, ...
- Help dealing with changes in software
  - Some part of a system is free to vary, independently from the rest

# MVC pattern defined

#### CONTROLLER Takes user input and figures out what it means to the model. MODEL The model holds all VIEW the data, state and Here's the creamy controller; it lives in application logic. The Gives you a presentation model is oblivious to of the model. The view the middle. the view and controller, usually gets the state although it provides an and data it needs to interface to manipulate display directly from and retrieve its the model. state and it can send (2) notifications of state changes to observers. Change your Controller (1) The user did state something 3 Change your display play()() rip() {} burn(){} I've changed! Model **V**iew (5)I need your state Here's the model; information This is the user it handles all application data interface. and logic.

## Normal life-cycle of interaction

- You're the user you interact with the view.
  The view is your window to the model. When you do something to the view (like click the Play button) then the view tells the controller what you did. It's the controller's job to handle that.
- The controller asks the model to change its state.

  The controller takes your actions and interprets them. If you click on a button, it's the controller's job to figure out what that means and how the model should be manipulated based on that action.
- The controller may also ask the view to change.
  When the controller receives an action from the view, it may need to tell the view to change as a result. For example, the controller could enable or disable certain buttons or menu items in the interface.
- The model notifies the view when its state has changed.

  When something changes in the model, based either on some action you took (like clicking a button) or some other internal change (like the next song in the playlist has started), the model notifies the view that its state has changed.
- The view asks the model for state.

  The view gets the state it displays directly from the model. For instance, when the model notifies the view that a new song has started playing, the view requests the song name from the model and displays it. The view might also ask the model for state as the result of the controller requesting some change in the view.

# Mapping concepts to JavaFX

- View: presenting the UI
  - FXML
  - The Nodes in the Scene Graph
- Controller: reacting to user actions
  - Set of event handlers
- Model: handling the data
  - Class(es) including data
  - Persistent data in Data Bases

# Design Exercise

- Imagine an application managing a list of items (e.g., names)
- Different items in the user interface should manage the same set of data, with different criteria and actions
- Where do you declare the data class?
- Which class should have access to which?
- Who creates what objects?

A possible Create solution <<Controller>> <<View>> Event ApplicationController Scene - model: Model + scene Graph Nodes - view: View + action handlers + get Values + set Values + setModel + lookup + setView get / set get / set / check <<Model>> DataList - list of names + create List + add Element + find Element + delete Element Application Create - model: Model - scene: View - controller: Controller —Create-+ start 21
