

# Collection Family Tree

# Set interface

---

- ▶ Add/remove elements
  - ▶ boolean **add**(element)
  - ▶ boolean **remove**(object)
- ▶ Search
  - ▶ boolean **contains**(object)
- ▶ No duplicates
- ▶ No positional Access!

# Notation

---

- ▶ A set stores *keys*
- ▶  $U$  – Universe of all possible keys
- ▶  $K$  – Set of keys actually stored

# Hash Table

---

- ▶ Devise a function to transform each *key* into an index
- ▶ Use an array

# Hash Function

---

- ▶ Is a function that maps data of arbitrary size to data of fixed size
- ▶ Mapping from  $\mathbf{U}$  to the slots of a hash table  $T[0\dots m-1]$ 
$$h : \mathbf{U} \rightarrow \{0, 1, \dots, m-1\}$$
- ▶  $h(k)$  is the “hash value” of key  $k$
- ▶ Main application:
  - ▶ Hash table
  - ▶ Cryptographic hash function
    - ▶ Authentication
    - ▶ Ensure file integrity (to avoid tampering)
    - ▶ Calculate digest for digital signature
    - ▶ *Used by Git too.*

# Hash Function

---

- ▶ Main properties:

- ▶ Hash table

- ▶ Deterministic: same key, same hash value

- ▶ Uniform: “Any key should be equally likely to hash into any of the  $m$  slots, independent of where any other key hashes to”

- ▶ Defined range

- ▶ Cryptographic hash function

- ▶ Collision resistance (large hash value) e.g. SHA-1 160 bit

- ▶ Non invertible: it is not possible to reconstruct  $k$  from  $h(k)$

# Hash Function

---

- ▶ Compression

- ▶  $h_N : \mathbf{U} \rightarrow \mathbf{N}^+$

- $$h(k) = h_N(k) \bmod m$$

- ▶ Expansion

- ▶  $h_R : \mathbf{U} \rightarrow [0, 1[ \in \mathbf{R}$

- $$h(k) = \lfloor h_R(k) \cdot m \rfloor$$

# Hash Function - Complexity

---

- ▶ Usually,  $h(k) = O(\text{length}(k))$ 
  - ▶  $\text{length}(k) \ll N \rightarrow h(k) = O(1)$

# A simple hash function

---

- ▶  $h : A \subseteq \mathbb{N}^+ \rightarrow [0, m-1]$
- ▶ Split the key into its “component”, then sum their integer representation
- ▶  $h_N(k) = h_N(x_0x_1x_2 \dots x_n) = \sum_{i=0}^n x_i$
- ▶  $h(k) = h_N(k) \% m$

# A simple hash (problems)

---

## ▶ Problems

▶  $h_N(\text{"NOTE"}) = 78+79+84+69 = 310$

▶  $h_N(\text{"TONE"}) = 310$

▶  $h_N(\text{"STOP"}) = 83+84+79+80 = 326$

▶  $h_N(\text{"SPOT"}) = 326$

## ▶ Problems (m = 173)

▶  $h(74,778) = 42$

▶  $h(16,823) = 42$

▶  $h(1,611,883) = 42$

# Collisions

# Collisions

---

- ▶ Collisions are possible!
- ▶ Multiple keys can hash to the same slot
  - ▶ Design hash functions such that collisions are minimized
- ▶ But avoiding collisions is impossible.
  - ▶ Birthday paradox
  - ▶ Design collision-resolution techniques
- ▶ Search will cost  $O(n)$  time in the worst case
- ▶ Hash value is an hint about where to start to search
- ▶ However, usually all operations can be made to have an expected complexity of  $O(1)$ .

# Birthday paradox

---

- ▶ Let's use birthday as hash function.
  - ▶ 365 slot in the array
  - ▶ Let's consider the probability of a collision

# Natural numbers

---

- ▶ An hash function may assume that the keys are natural numbers
- ▶ When they are not, have to “interpret” them as natural numbers

# Natural numbers hashing

---

- ▶ Division Method (compression)

$$h(k) = k \bmod m$$

- ▶ Pros

- ▶ Fast, since requires just one division operation

- ▶ Cons

- ▶ Have to avoid certain values of  $m$

- ▶ Good choice for  $m$  (recipe)

- ▶ Prime

- ▶ Not “too close” to powers of 2
- ▶ Not “too close” to powers of 10

# Natural numbers hashing

---

## ▶ Multiplication Method II

$$h(k) = k \cdot 2,654,435,761$$

### ▶ Pros

- ▶ Works well for addresses

### ▶ Caveat (Donald Knuth)

- ▶  $2,654,435,761 = \frac{2^{32}}{\textit{golden ratio}}$

# Resolution of collisions

## ▶ Open Addressing

- ▶ When collisions occur, use a systematic (consistent) procedure to store elements in free slots of the table
- ▶ “Double hashing”, “linear probing”, ...

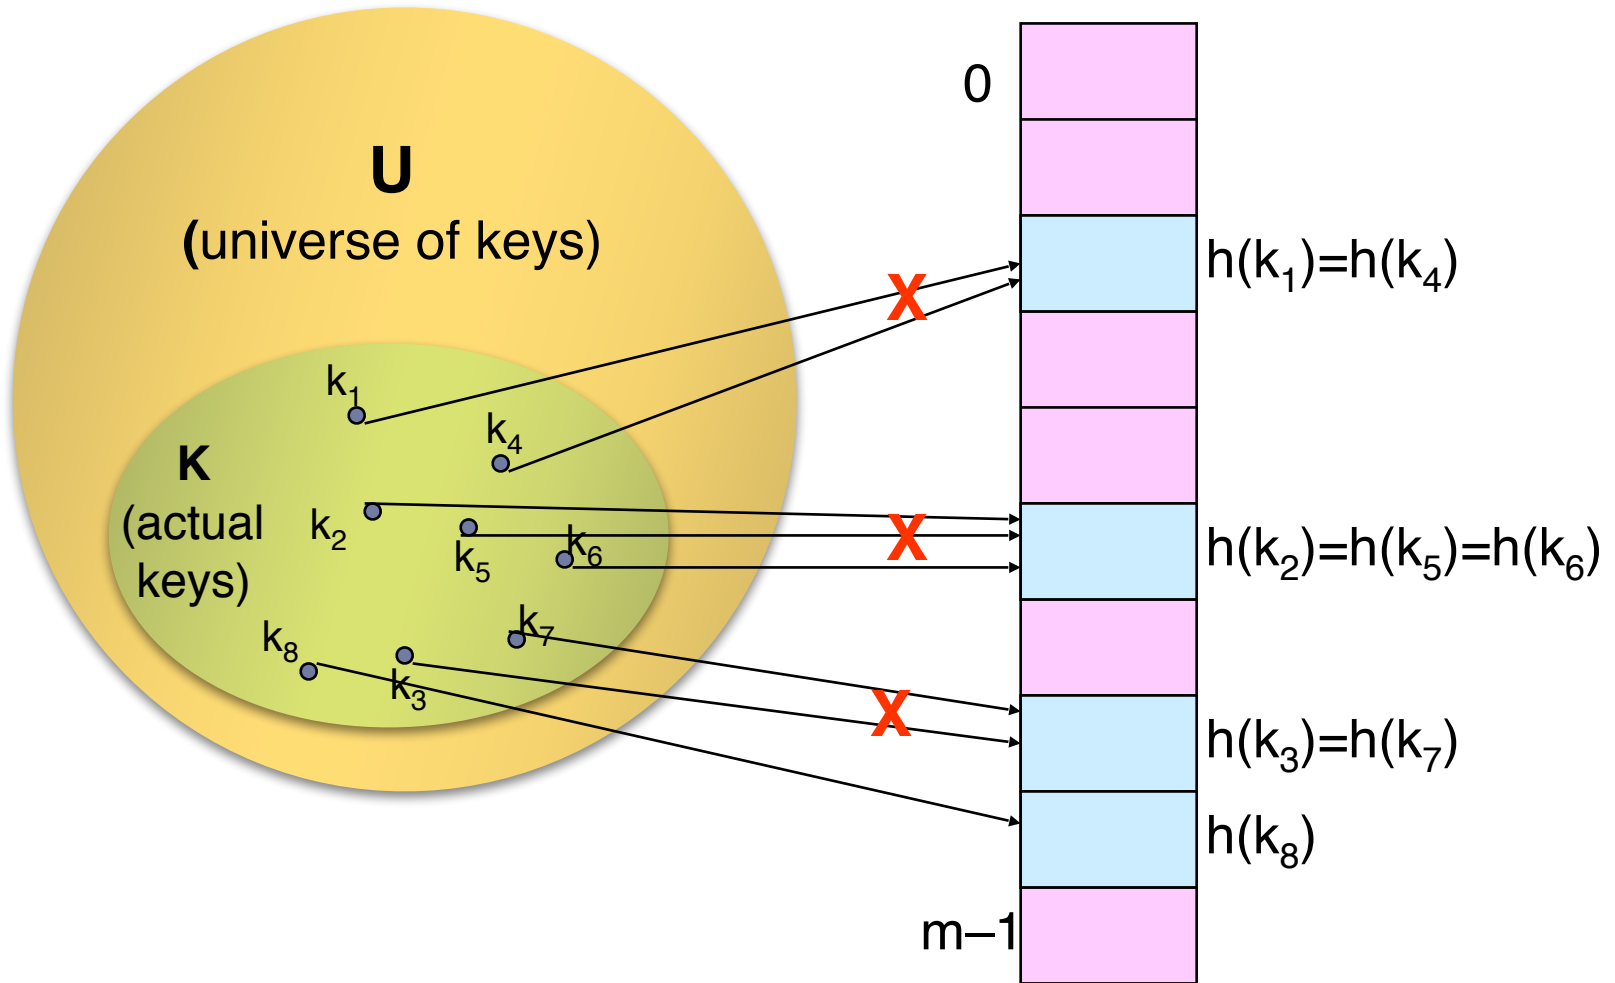

## ▶ Chaining

- ▶ Store all elements that hash to the same slot in a linked list

# Chaining

# Chaining

# Chaining (analysis)

---

- ▶ Load factor  $\alpha = n/m =$  average keys per slot
  - ▶  $n$  – number of elements stored in the hash table
  - ▶  $m$  – number of slots
- ▶ If  $n < m$ , very few slots should have more than one entry
- ▶ Even if  $n < m$ , collision occurs (birthday paradox)

# Chaining (analysis)

---

- ▶ Worst-case complexity:

$O(n)$  ( + time to compute  $h(k)$  )

# Chaining (analysis)

---

- ▶ Average depends on how  $h(\cdot)$  distributes keys among  $m$  slots
- ▶ Let assume
  - ▶ Any key is equally likely to hash into any of the  $m$  slots
  - ▶  $h(k) = O(1)$
- ▶ Expected length of a linked list = load factor =  $\alpha = n/m$
- ▶  $\text{Search}(x) = O(\alpha) + O(1) \approx O(1)$

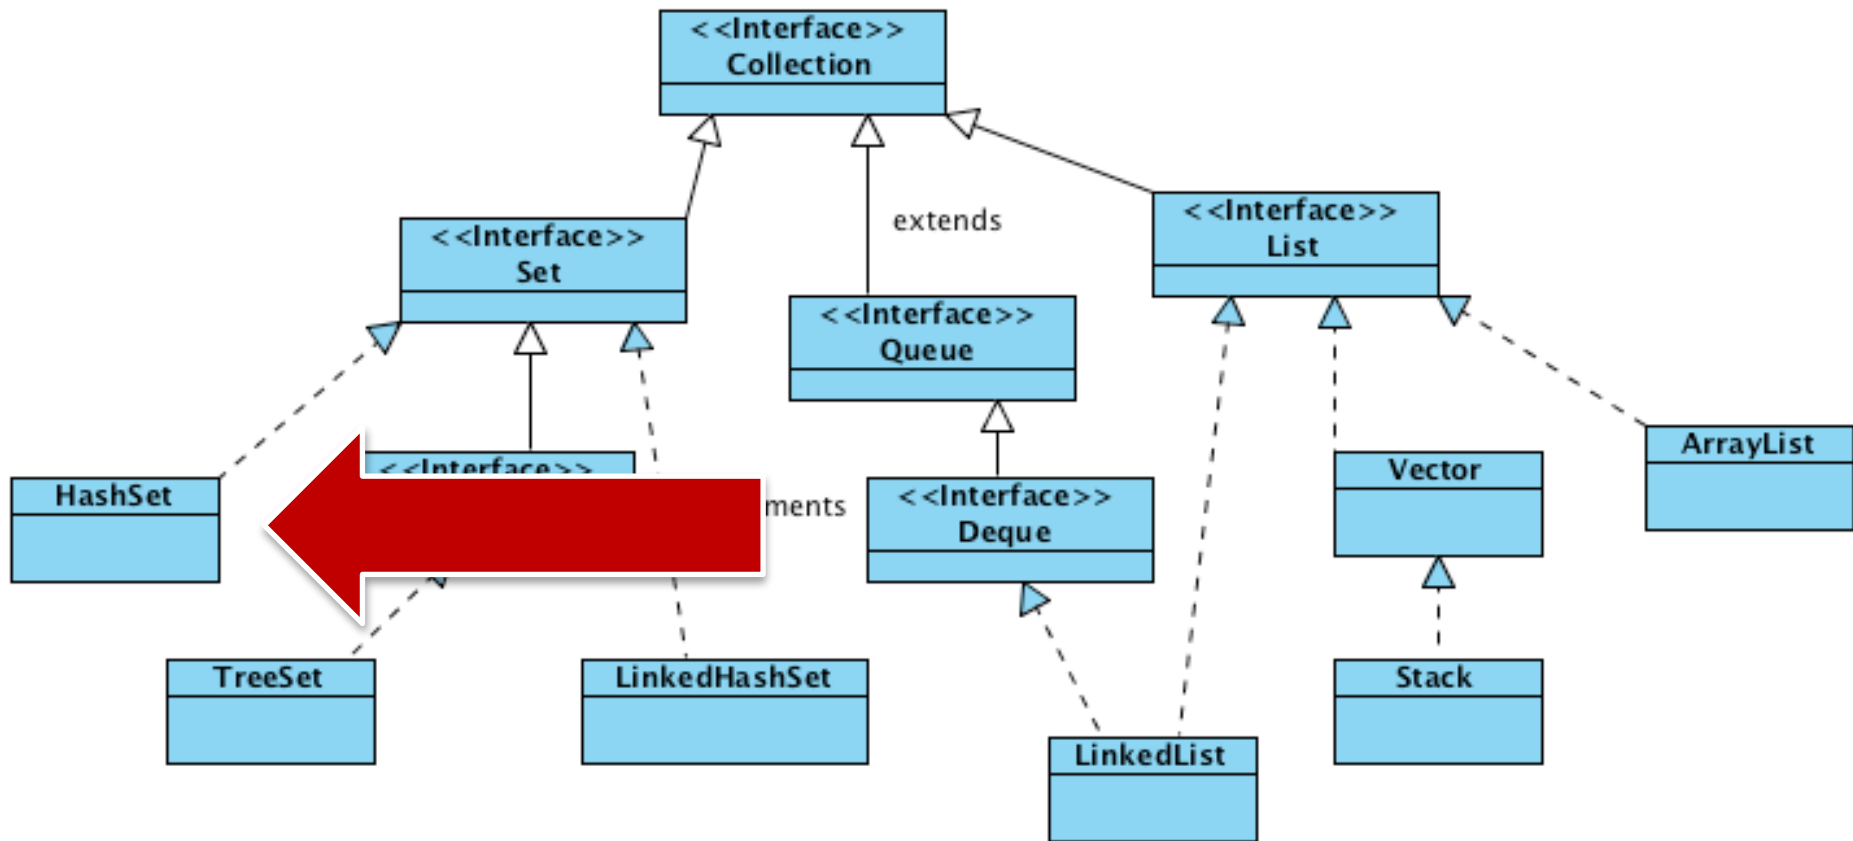

# A note on iterators

---

- ▶ **Collection** extends **Iterable**
- ▶ An **Iterator** is an object that enables you to traverse through a collection (and to remove elements from the collection selectively)
- ▶ You get an Iterator for a collection by calling its `iterator()` method

```
public interface Iterator<E> {  
    boolean hasNext();  
    E next();  
    void remove(); //optional  
}
```

# Collection Family Tree

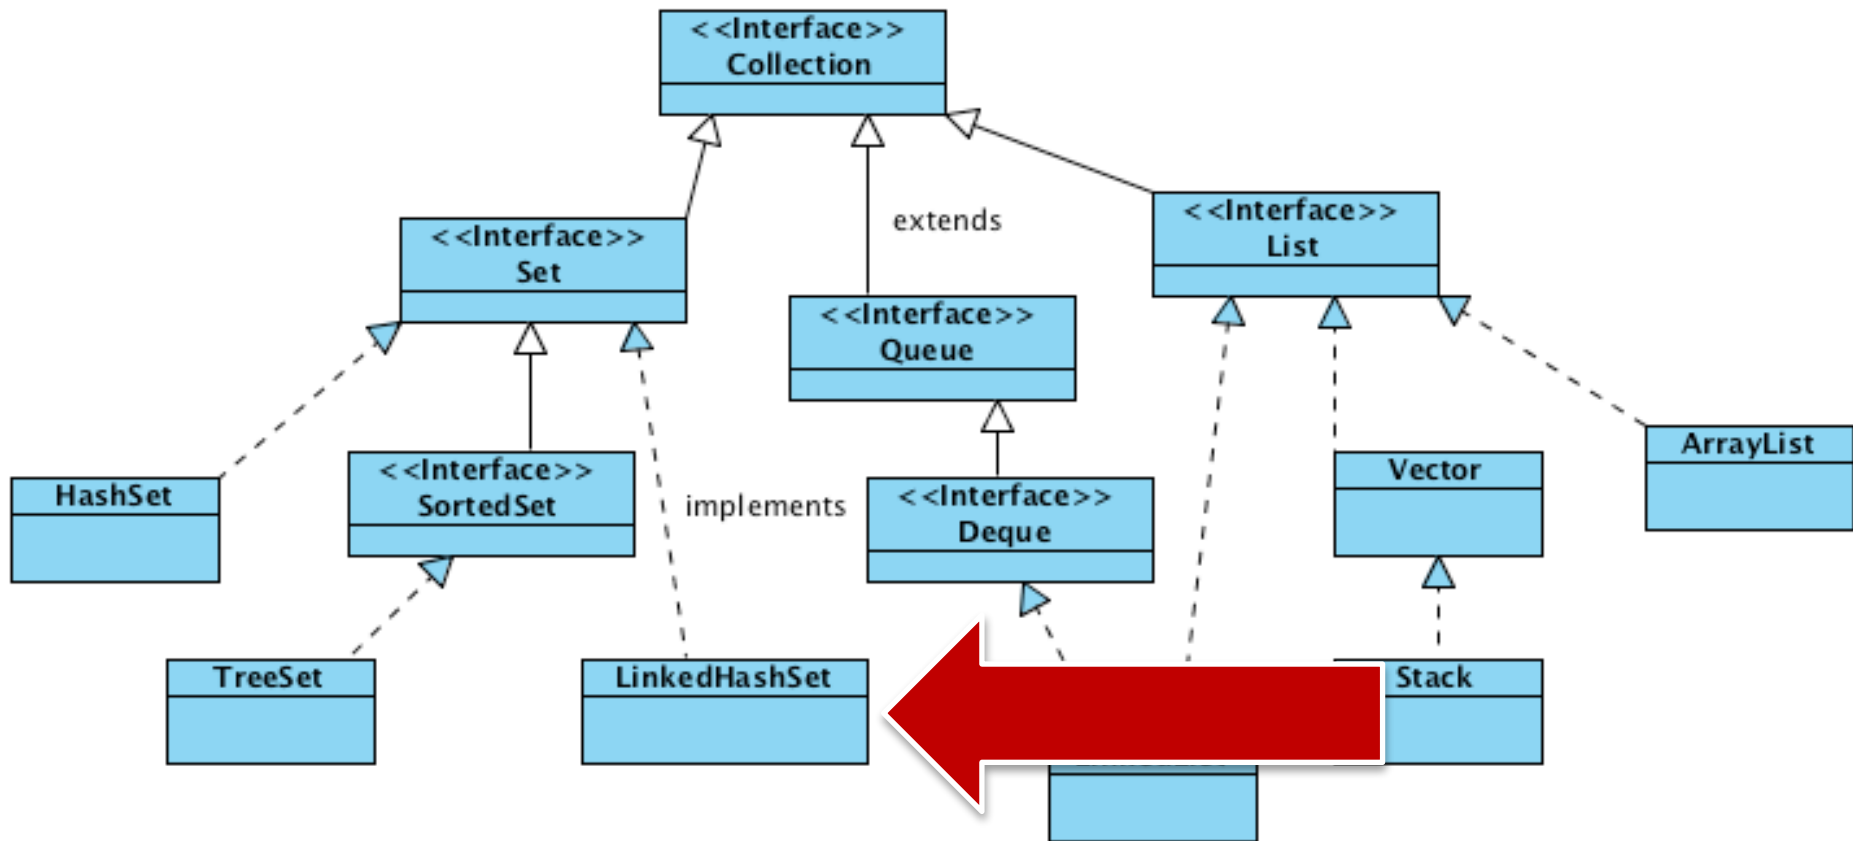

# HashSet

- ▶ Add/remove elements
  - ▶ boolean **add**(element)
  - ▶ boolean **remove**(object)
- ▶ Search
  - ▶ boolean **contains**(object)
- ▶ No duplicates
- ▶ No positional Access
- ▶ Unpredictable iteration order!

# Collection Family Tree

# LinkedHashSet

- ▶ Add/remove elements
  - ▶ boolean **add**(element)
  - ▶ boolean **remove**(object)
- ▶ Search
  - ▶ boolean **contains**(object)
- ▶ No duplicates
- ▶ No positional Access
- ▶ **Predictable** iteration order

# Costructors

---

- ▶ `public HashSet()`
- ▶ `public HashSet(Collection<? extends E> c)`
- ▶ `HashSet(int initialCapacity)`
- ▶ `HashSet(int initialCapacity, float loadFactor)`

# Costructors

---

- ▶ `public HashSet()`
- ▶ `public HashSet(int initialCapacity)`
- ▶ `public HashSet(int initialCapacity, float loadFactor)`
- ▶ `public HashSet(Collection<? extends E> c)`

# JCF's HashSet

---

- ▶ Built-in hash function
- ▶ Dynamic hash table resize
- ▶ Smoothly handles collisions (chaining)
- ▶  $O(1)$  operations (well, usually)
- ▶ Take it easy!

# Default hash function in Java

```
public boolean equals(Object obj);  
public int hashCode();
```

- ▶ If two objects **are equal** according to the `equals()` method, then `hashCode()` must produce the same result
- ▶ If two objects **are not equal** according to the `equals()` method, performances are better whether the `hashCode()` produces different results

# Hash functions in Java

```
public boolean equals(Object obj);  
public int hashCode();
```

**hashCode()** and **equals()**  
should always be defined  
together

MATT GROENING

# Hash functions in Java

---

- ▶ `public int hashCode()`
  - ▶ returns a 32-bit signed integer
    - ▶ 32-bit Float or 32-bit Integer could be used directly
    - ▶ Perfect hash function: map each input to a different hash value
  - ▶ Eclipse provides a convenient method to automatically generate `equals()` and `hashCode()` implementation

MATT GROENING

# Recap

---

## ▶ == or !=

- ▶ Used to compare the references of two objects

```
MyData foo = new MyData();
MyData bar = new MyData();

if(foo != bar) {
    System.out.println("References are different");
}

if(foo == bar){
    System.out.println("References are equal");
}
```

# Recap

---

## ▶ equals()

- ▶ Used to give **equality** information about the objects

```
MyData foo = new MyData();
MyData bar = new MyData();

if(foo.equals(bar)) {
    System.out.println("Objects have the same values");
} else {
    System.out.println("Objects have different values");
}
```

# Recap

---

- ▶ **hashCode()**
  - ▶ Return the hash value of an object
  - ▶ Must behave in a way consistent with the same object `equals()` method

```
MyData foo = new MyData();
MyData bar = new MyData();

if(foo.equals(bar)) {
    if(foo.hashCode() == bar.hashCode()) {
        System.out.println("Hash code must be equal")
    }
}
```

# Recap

---

- ▶ **compareTo()**
  - ▶ Gives the ordering of objects
  - ▶ Must be used only if need to order the object in a collection

```
MyData foo = new MyData();  
MyData bar = new MyData();  
  
if (foo.compareTo(bar) == 0) {  
    // WRONG!!  
}
```

# Implementing your own hash functions

---

- ▶ Grab your hash function from a professional
